Bicuspidal Geodesics on Punctured Hyperbolic Surfaces

- Length and angle
  - (= Riemannian metric)
- Straight lines
  - (= Geodesics)
- How many \_\_\_\_\_ geodesics are there? (Change the question until it is interesting)

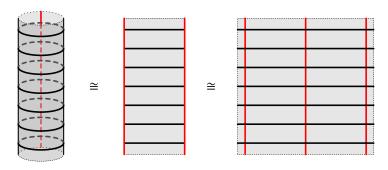

## Geodesics on flat surfaces

Geodesics on surface ↔ Geodesics on plane

## Counting geodesics on the cylinder

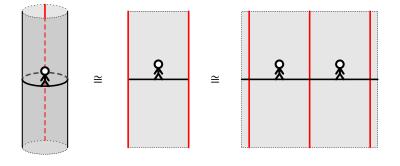

How many **closed** geodesics are there?

Infinitely many

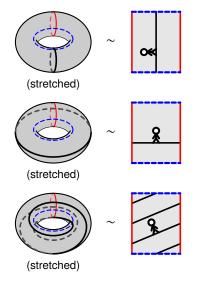

## Counting geodesics on the cylinder

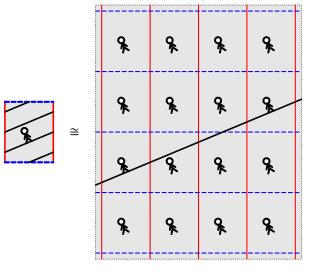

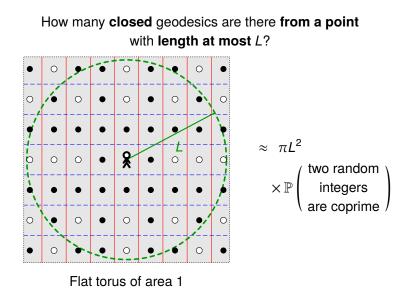

Exactly two

How many closed geodesics are there from a point?

One per pair of coprime integers (m, n)

$$\mathbb{P}(\text{both divisible by } p) = \frac{1}{p^2}$$
$$\mathbb{P}(\text{not both divisible by } p) = 1 - \frac{1}{p^2}$$
$$\mathbb{P}(\text{coprime}) = \prod_{\substack{p \text{ prime}}} \left(1 - \frac{1}{p^2}\right)$$
$$= \frac{1}{\zeta(2)}$$

$$\# \left\{ \begin{array}{c} \text{closed geodesics from a point} \\ \text{with length at most } L \end{array} \right\} \sim \frac{1}{\zeta(2)} \pi L^2$$

$$\sim \frac{1}{\zeta(2)}\pi L^2$$

#### Theorem (Eskin-Masur-Zorich 2003)

#

Let  $\mathcal{H}$  be the space of all flat surfaces of area 1 with prescribed conical singularities. Then for almost every surface S in  $\mathcal{H}$ ,

 $\# \left\{ \begin{array}{c} \text{maximal cylinders of closed geodesics} \\ \text{with length at most } L \end{array} \right.$ 

$$\sim c_{\mathcal{H}} \pi L^2$$
,

where  $c_{\mathcal{H}}$  is a constant that can be explicitly computed from  $\mathcal{H}$ .

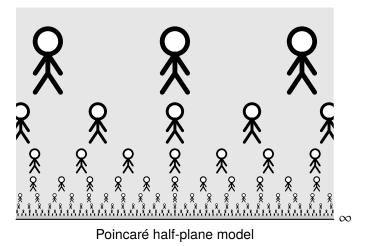

For 
$$\mathcal{H} = \{$$
flat tori $\}$ , we can compute  $c_{\mathcal{H}} = \frac{6}{\pi^2}$ .

#### Corollary

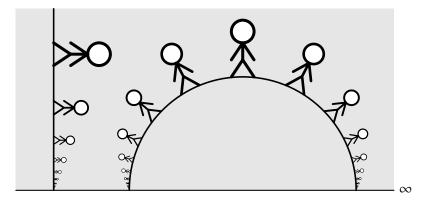

$$\zeta(2)=\frac{\pi^2}{6}.$$

# Hyperbolic surfaces

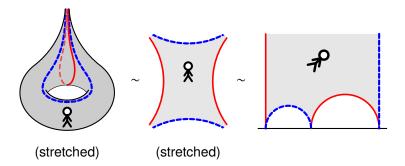

Gaussian curvature  $\equiv -1$ Can be evenly covered by the hyperbolic plane

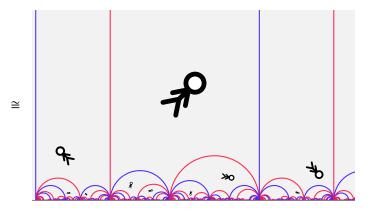

## Geodesics on the hyperbolic plane

# Hyperbolic surfaces

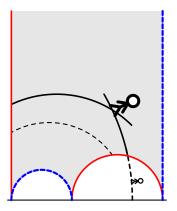

## Hyperbolic surfaces

# Counting geodesics on hyperbolic surfaces

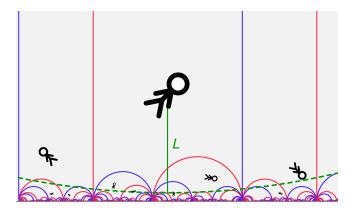

How many closed geodesics are there from a point?

Sometimes, none! (Usually, there's one nearby.)

## Counting geodesics on hyperbolic surfaces

How many **closed** geodesics are there with **length at most** *L*?

#### Guess: exponential in L?

### Prime Geodesic Theorem (Sarnak 1980)

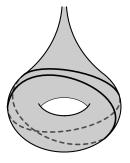

On a closed hyperbolic surface with finite area,

 $\# \left\{ \begin{array}{c} \text{closed geodesics} \\ \text{with length at most } L \end{array} \right\} \sim \frac{e^L}{L}.$ 

Compare with the prime number theorem:

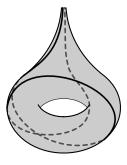

$$\#\{\text{primes} \le n\} \sim \frac{n}{\log n}$$

## Another type of geodesic

(stretched)

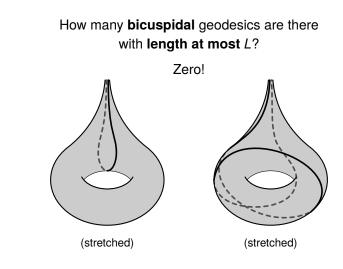

closed geodesics

(stretched)

bicuspidal geodesics

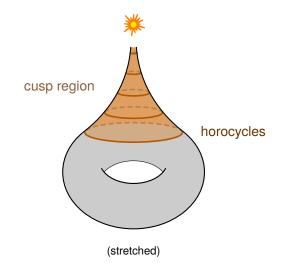

# Counting bicuspidal geodesics

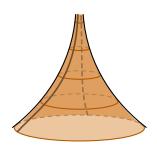

But clearly some are "longer" than others...

### An explosion occurs at the cusp

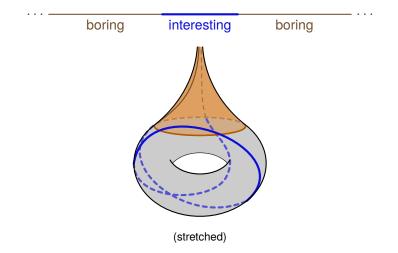

Bounded by horocycle of length 2 All cusp regions are congruent Wave front  $\perp$  Propagation  $\downarrow$ Horocycles  $\perp$  Geodesics

#### Collar theorem

The cusp regions on a hyperbolic surface are pairwise disjoint.

#### Definition

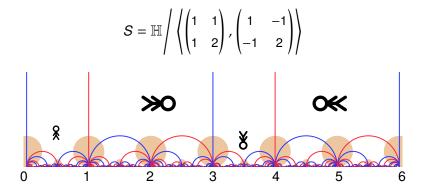

#### Normalised length = length of interesting part

Ang Yan Sheng

#### Bicuspidal Geodesics on Punctured Hyperbolic Surfaces 23/30

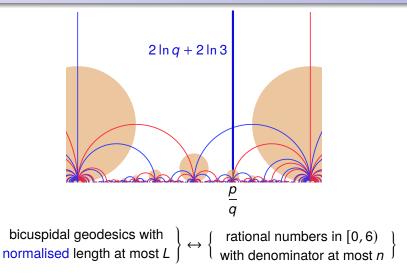

# How many **bicuspidal** geodesics are there with **normalised length at most** *L*?

## Example: the modular torus

Map repeats every 6 units Images of cusp:  $\mathbb{Q} \cup \{\infty\}$ 

## Example: the modular torus

 $(L = 2\ln n + 2\ln 3)$ 

$$\# \left\{ \begin{array}{l} \text{rational numbers in } [0, 6) \\ \text{with denominator at most } n \end{array} \right\}$$
$$= \# \left\{ 0 \le \frac{p}{q} < 6 : q \le n \right\}$$
$$= \# \left\{ p, q \text{ coprime } : 0 \le p < 6q, q \le n \right\}$$
$$\sim \frac{1}{2}(n)(6n) \times \mathbb{P} \left( \begin{array}{l} \text{two random integers} \\ \text{are coprime} \end{array} \right)$$
$$= \frac{3}{\zeta(2)}n^2.$$

# How many **bicuspidal** geodesics are there with **normalised length at most** *L*?

#### Main Theorem

Let *S* be a hyperbolic surface with genus *g* and *p* punctures. Let *C*<sub>1</sub> and *C*<sub>2</sub> be any cusp regions on *S*. Then $\# \left\{ \begin{array}{c} \text{bicuspidal geodesics from } C_1 \text{ to } C_2 \\ \text{with normalised length at most } L \end{array} \right\} \sim c_S e^L,$ where  $c_S = \frac{2}{2}$ 

where 
$$c_S = \frac{1}{(2g - 2 + p)\pi^2}$$
.

Example: the modular torus

 $\# \left\{ \begin{array}{c} \text{bicuspidal geodesics with} \\ \text{normalised length at most } L \end{array} \right\}$ 

$$\sim \frac{2}{(2g-2+p)\pi^2} = \frac{2}{\pi^2} e^L \qquad (g = 1, p = 1) = \frac{18}{\pi^2} n^2 \qquad (L = 2\ln n + 2\ln 3) \\ \sim \frac{3}{\zeta(2)} n^2$$

Corollary

$$\zeta(2)=\frac{\pi^2}{6}.$$

## Proof sketch

$$\# \left\{ \begin{array}{c} \text{returns to cusp region} \\ \text{after time } L \end{array} \right\} = \# \left\{ \begin{array}{c} \text{bicuspidal geodesics with} \\ \text{normalised length at most } L \end{array} \right.$$

## Proof sketch

#### Theorem (Zagier 1981, Sarnak 1981)

Long horocycles equidistribute with respect to area.

 $\begin{array}{c} \text{proportion of wave front} \\ \text{in cusp region} \end{array} \rightarrow \frac{\text{Area}(\text{cusp region})}{\text{Area}(\text{surface})} \end{array}$
